Tense Manages to Predict Implicative Behavior in Verbs

Ellie Pavlick  Chris Callison-Burch
Computer and Information Science Department
University of Pennsylvania

Abstract
Implicative verbs (e.g. manage) entail their compliment clauses, while non-implicative verbs (e.g. want) do not. For example, while managing to solve the problem entails solving the problem, no such inference follows from wanting to solve the problem. Differentiating between implicative and non-implicative verbs is therefore an essential component of natural language understanding, relevant to applications such as textual entailment and summarization. We present a simple method for predicting implicativeness which exploits known constraints on the tense of implicative verbs and their compliments. We show that this yields an effective, data-driven way of capturing this nuanced property in verbs.

1 Overview
Understanding language requires the ability to perform basic inference–to make conclusions about what is likely true or false based on what is said. For example, given the sentence She fixed the bug, we should almost certainly infer that the bug is fixed. However, rather than stating plainly that She fixed the bug, one might instead say:

(1a) She managed to fix the bug before midnight.
(1b) She happened to fix the bug while refactoring.

Implicative verbs, like those in (1), give rise to entailments, while non-implicative verbs, like those in (2), do not. It is therefore vital to natural language understanding to differentiate between clauses that are embedded under implicatives, which we can often infer to be either true or false, and those which are embedded under non-implicatives, for which such inferences cannot be made. In this paper, we exploit a known linguistic property of implicative verbs— that their compliment clause is constrained to be in the same tense as the main clause— in order to predict the tendency of verbs to behave implicatively. We show that our method almost perfectly separates non-implicatives from implicatives in a small hand-labeled dataset, and that it provides strong signal for predicting entailments in sentences involving implicative verbs.

2 Implicative Verbs
Some English verbs can take infinitival compliments, meaning they can appear in constructions of the form \( VB_1^* \) to \( VB_2 \), where \( VB_1^* \) is the “main” verb (which can be conjugated\(^1\)) and \( VB_2 \) is the “compliment” verb (which is in infinitive form). Examples (1a)-(2b) illustrate verbs taking infinitive compliments.

Implicative verbs are a special subclass\(^2\) of such verbs which give rise to entailments involving their

\(^1\)Here, * indicates that \( VB_1 \) can match any verb form, e.g. \( VB, VBD, VBP \), etc. \( VB_2 \) can only match the base form \( VB \).
\(^2\)We note that factive verbs represent another special class of verbs which can take infinitival compliments. Unlike implica-
Table 1: Implicative verbs give rise to entailments involving their compliment clauses. Non-implicatives entail neither the truth nor the falsity of their compliments, and thus the truth/falsity of the compliment is unaffected by negation of the main clause.

<td>I did not want to solve the problem. ∉ 1 did not solve the problem.</td>
</tr>
</tbody>
</table>

compliment clauses. Individual implicatives can differ in the entailments they generate: e.g. while manage entails the truth of its compliment, fail entails the falsity of its compliment (failed to solve the problem ⇒ didn’t solve the problem). Despite these differences, however, implicatives represent a coherent class of verbs in that they permit some inference to be made about their compliments, and this inference is sensitive to the context (positive/negated) of the main clause. This contrasts with non-implicatives, like want, which do not permit any inference regarding their compliments, and for which the truth of the compliment is unaffected by negation in the main clause (Table 1).

The method described in this paper aims to separate implicatives from non-implicatives (manage vs. want), rather than to differentiate between types implicatives (manage vs. fail). Making this implicative/non-implicative distinction is a necessary first step toward handling inferences involving embedded clauses, and one that, to date, has only been performed using manually-constructed word lists (?; ?).

2.1 Tense constraints on compliment clauses

We exploit this property to predict implicativeness—whether the truth of a verb’s compliment can be inferred—by observing the verb’s usage in practice.

3 Method

We hypothesize that, given a large corpus, we should be able to distinguish implicative verbs from non-implicatives by observing how often the main verb tense agrees/disagrees with the tense of the compliment clause. Unfortunately, verbs in infinitival compliment clauses are not conjugated, and so are not necessarily marked for tense. We therefore use the Stanford Temporal Tagger (TT) (?) in order to identify time-referring expressions (e.g. tomorrow or last night) and resolve them to either past, present, or future tense.

We find all sentences containing VB1* to VB2 constructions in the Annotated Gigaword corpus (?). We run the the TT over all of the sentences in order to identify time-referring expressions. We only consider sentences in which a time-referring expression appears and is in a direct dependency relationship with the compliment verb (VB2). We provide the TT with the document publication dates,\(^3\) which are used to resolve each time mention to a specific calendar date and time. We then map these time expressions coarsely to either past, present, or future tense by comparing the resolved time to the document creation time. Because of the fact that days

\(^3\)Provided as metadata in the Annotated Gigaword.
were often not resolved correctly, or at all, we eventually throw away sentences in which the compliment clause is labeled as present tense, as these are rarely true references to the present, and rather the result of incorrect time resolution, or implicit future references (e.g. *I am going to solve the problem today* implies the future as in *later today*, but this is not captured by the TT). We also assign the main clause to past, present, or future tense by using the fine-grained POS tag and a set of heuristics (for example, to check for modals).\(^4\)

We assign a *tense agreement* score to each verb \(v\) as follows. Let \(S\) be the set of all \(VB_1^*\) to \(VB_2\) constructions in which \(VB_1^* \equiv v\). Then tense agreement is simply \(\frac{1}{|S|} \times |\{s \in S \mid \text{compliment tense} = \text{main tense}\}|\), i.e. the fraction of constructions in \(S\) in which the tenses of the main and compliment clauses agree. We expect implicative verbs to occur mostly in agreeing constructions, and thus have high tense agreement, while non-implicatives may occur in both agreeing and non-agreeing constructions, and thus should have lower tense agreement. Note that while in theory, implicatives should never appear in non-agreeing constructions, the time annotation process is very imprecise, and thus we do not expect perfect results.

### 4 Evaluation

**Recreating list from Karttunen (1971)**\(^5\) provides a short illustrative list of 7 known implicatives and 8 non-implicatives (shown in Table 2). As a first evaluation, we test whether tense agreement can accurately separate the verbs in this list, such that the implicatives are assigned higher agreement scores than the non-implicatives. Table 2 shows that this is indeed the case. Tense agreement almost perfectly divides the list, with implicative verbs appearing above non-implicative verbs in all cases. The one exception is *decide* (reportedly non-implicative), which appears above *dare* (reportedly implicative). This error, however, seems understandable: while *decide* is not strictly implicative in the way *manage* is, it is often used as an implicative. E.g. the sentence *I decided to leave* would likely be taken to mean *I left*.

<table>
<thead>
<tr>
<th>Verb</th>
<th>Tense Agreement Score</th>
</tr>
</thead>
<tbody>
<tr>
<td>venture to</td>
<td>1.00</td>
</tr>
<tr>
<td>forget to</td>
<td>0.80</td>
</tr>
<tr>
<td>manage to</td>
<td>0.79</td>
</tr>
<tr>
<td>bother to</td>
<td>0.61</td>
</tr>
<tr>
<td>happen to</td>
<td>0.59</td>
</tr>
<tr>
<td>get to</td>
<td>0.52</td>
</tr>
<tr>
<td>decide to</td>
<td>0.45</td>
</tr>
<tr>
<td>dare to</td>
<td>0.44</td>
</tr>
</tbody>
</table>

*Table 2: Tense agreement scores for known implicatives (bold) and non-implicatives listed in ?).* Ranking by tense agreement almost perfectly divides the two classes.

**Predicting entailment** Our interest is not in distinguishing implicatives from non-implicatives for its own sake, but rather to predict, based on the main verb, whether the truth of the compliment can be inferred. We therefore conduct a second evaluation to assess how well tense agreement predicts this entailment property. We design our evaluation following the recognizing textual entailment (RTE) task\(^6\), in which two sentences are given, a premise \(p\) and a hypothesis \(h\), and the goal is to determine whether \(p\) reasonably entails \(h\). To construct our \(p/h\) pairs, we take all the verbs extracted in Section 3 which appear in at least 50 tense-labeled sentences. For each of these verbs, we choose 3 random sentences in which the verb appears as \(VB_1^*\) in a \(VB_1^*\) to \(VB_2\) construction.\(^6\) From each sentence, we extract the compliment clause by deleting \(VB_1^*\) to from the sentence, and conjugating \(VB_2\) to match the tense of \(VB_1^*\). We then use the original sentence as \(p\) and the extracted compliment as \(h\): e.g. a \(p/h\) pair might look like *I get to interact with fellow professors*/ *I interact with fellow professors*. We ask 5 independent annotators on Amazon Mechanical Turk to read each \(p\) and then determine whether \(h\) is true, false, or unclear given \(p\).\(^7\) We take the majority answer as the true label. We expect that implicative verbs should lead to judgements which are decidedly true or false while non-implicatives should lead to mostly judgements of unclear.

---

\(^4\)Full set of heuristics in supplementary material.

\(^5\)The original list had 8 implicatives, but we omit *remember* since, in our data, it occurred almost exclusively with recurring time expressions, which we were not able to map to a specific date/time and thus tense, e.g. *consumers must remember to make payments every 14 days.*

\(^6\)These sentences can come from anywhere in the Gigaword corpus, they are not required to contain time expressions.

\(^7\)Full annotation guidelines in supplementary material.
Figure 1 shows that these expectations hold. When a verb with low tense agreement appeared as the main verb of a sentence, the truth of the compliment could only be inferred 30% of the time. When a verb with high tense agreement appeared as the main verb, the truth of the compliment could be inferred 91% of the time. This difference is significant at $p < 0.01$. That is, tense agreement provides a strong signal for identifying non-implicative verbs, and thus can help systems avoid false-positive entailment judgements, e.g. incorrectly inferring that wanting to merge $\Rightarrow$ merging.

Interestingly, tense agreement accurately models verbs that are not implicative by definition, but which nonetheless tend to behave implicatively in practice. For example, our method finds high tense agreement for choose to and be allowed to, which are often used to communicate, albeit indirectly, that their compliments did in fact happen. To convince ourselves that treating such verbs as implicatives makes sense in practice, we manually look through the RTE3 dataset (?) for examples containing high-scoring verbs according to our method. Table 3 shows some example inferences that hinge precisely on recognizing these types of de facto implicatives.

## 5 Discussion and Related Work

Language understanding tasks such as RTE (?, ?) and bias detection (?) have been shown to require knowledge of implicative verbs, but such knowledge has previously come from manually-built word lists rather than from data. (?) and ? describe automatic systems to handle implicatives, but require hand-crafted rules for each unique verb that is handled. The tense agreement method we present offers a starting point for acquiring such rules from data, and is well-suited for incorporating into statistical systems. The clear next step is to explore similar data-driven means for learning the specific behaviors of individual implicative verbs, which has been well-studied from a theoretical perspective (?; ?; ?; ?). Another interesting extension concerns the role of tense in word representations. While currently, tense is rarely built directly into distributional representations of words (?; ?), our results suggest it may offer important insights into the semantics of individual words. We leave this question as a direction for future work.

## 6 Conclusion

Differentiating between implicative and non-implicative verbs is important for discriminating inferences that can and cannot be made in natural language. We have presented a data-driven method that captures the implicative tendencies of verbs by exploiting the tense relationship between the verb and its compliment clauses. This method effectively separates known implicatives from known non-implicatives, and, more importantly, provides good predictive signal in an entailment recognition task.
