Constrained Optimization

In many practical situations, we need to look for local extrema of a function J under additional constraints. This situation can be formalized conveniently as follows. We have a function $J \colon \Omega \to \mathbb{R}$ defined on some open subset Ω of a normed vector space, but we also have some subset U of Ω , and we are looking for the local extrema of J with respect to the set U.

Constrained Optimization

In many practical situations, we need to look for local extrema of a function J under additional constraints. This situation can be formalized conveniently as follows. We have a function $J\colon \Omega \to \mathbb{R}$ defined on some open subset Ω of a normed vector space, but we also have some subset U of Ω , and we are looking for the local extrema of J with respect to the set U.

The elements $u \in U$ are often called *feasible solutions* of the optimization problem consisting in finding the local extrema of some objective function J with respect to some subset U of Ω defined by a set of constraints. Note that in most cases, U is *not* open. In fact, U is usually closed.

Constrained Local Extrema

Definition. If $J: \Omega \to \mathbb{R}$ is a real-valued function defined on some open subset Ω of a normed vector space E and if U is some subset of Ω , we say that J has a *local minimum* (or *relative minimum*) at the point $u \in U$ with respect to U if there is some open subset $W \subseteq \Omega$ containing u such that

$$J(u) \le J(w)$$
 for all $w \in U \cap W$.

Constrained Local Extrema

Definition. If $J: \Omega \to \mathbb{R}$ is a real-valued function defined on some open subset Ω of a normed vector space E and if U is some subset of Ω , we say that J has a *local minimum* (or *relative minimum*) at the point $u \in U$ with respect to U if there is some open subset $W \subseteq \Omega$ containing u such that

$$J(u) \le J(w)$$
 for all $w \in U \cap W$.

Similarly, we say that J has a local maximum (or relative maximum) at the point $u \in U$ with respect to U if there is some open subset $W \subseteq \Omega$ containing u such that

$$J(u) \ge J(w)$$
 for all $w \in U \cap W$.

In either case, we say that J has a local extremum at u with respect to U.

Equality Constraints

In order to find necessary conditions for a function $J\colon \Omega \to \mathbb{R}$ to have a local extremum with respect to a subset U of Ω (where Ω is open), we need to incorporate the definition of U into these conditions. This can be done when the set U is defined by a set of equations,

$$U = \{ x \in \Omega \mid \varphi_i(x) = 0, \ 1 \le i \le m \},\$$

where the functions $\varphi_i \colon \Omega \to \mathbb{R}$ are continuous (and usually differentiable).

Equality Constraints

In order to find necessary conditions for a function $J\colon \Omega\to\mathbb{R}$ to have a local extremum with respect to a subset U of Ω (where Ω is open), we need to incorporate the definition of U into these conditions. This can be done when the set U is defined by a set of equations,

$$U = \{ x \in \Omega \mid \varphi_i(x) = 0, \ 1 \le i \le m \},\$$

where the functions $\varphi_i \colon \Omega \to \mathbb{R}$ are continuous (and usually differentiable).

The equations $\varphi_i(x) = 0$ are called *equality constraints*.

In the case of equality constraints, a *necessary condition* for a local extremum with respect to U can be given in terms of *Lagrange multipliers*.

Theorem (Necessary condition for a constrained extremum in terms of Lagrange multipliers). Let Ω be an open subset of \mathbb{R}^n , consider m C^1 -functions $\varphi_i \colon \Omega \to \mathbb{R}$ (with $1 \le m < n$), let

$$U = \{ v \in \Omega \mid \varphi_i(v) = 0, \ 1 \le i \le m \},\$$

and let $u \in U$ be a point such that the derivatives $d\varphi_i(u) \in \mathcal{L}(\mathbb{R}^n;\mathbb{R})$ are linearly independent; equivalently, assume that the $m \times n$ matrix $\left((\partial \varphi_i/\partial x_i)(u)\right)$ has rank m.

If $J: \Omega \to \mathbb{R}$ is a function which is differentiable at $u \in U$ and if J has a local constrained extremum at u, then there exist m numbers $\lambda_i(u) \in \mathbb{R}$, uniquely defined, such that

$$dJ(u) + \lambda_1(u)d\varphi_1(u) + \cdots + \lambda_m(u)d\varphi_m(u) = 0;$$

If $J: \Omega \to \mathbb{R}$ is a function which is differentiable at $u \in U$ and if J has a local constrained extremum at u, then there exist m numbers $\lambda_i(u) \in \mathbb{R}$, uniquely defined, such that

$$dJ(u) + \lambda_1(u)d\varphi_1(u) + \cdots + \lambda_m(u)d\varphi_m(u) = 0;$$

or equivalently,

$$\nabla J(u) + \lambda_1(u)\nabla \varphi_1(u) + \cdots + \lambda_m(u)\nabla \varphi_m(u) = 0.$$

Lagrange Multipliers

Definition. The numbers $\lambda_i(u)$ involved in the preceding theorem are called the *Lagrange multipliers* associated with the constrained extremum u.

Lagrange Multipliers

Definition. The numbers $\lambda_i(u)$ involved in the preceding theorem are called the *Lagrange multipliers* associated with the constrained extremum u.

The linear independence of the linear forms $d\varphi_i(u)$ is equivalent to the fact that the Jacobian matrix $\left((\partial \varphi_i/\partial x_j)(u)\right)$ of $\varphi=(\varphi_1,\ldots,\varphi_m)$ at u has rank m. If m=1, the linear independence of the $d\varphi_i(u)$ reduces to the condition $\nabla \varphi_1(u) \neq 0$.

The Lagrangian

A fruitful way to reformulate the use of Lagrange multipliers is to introduce the notion of the Lagrangian associated with our constrained extremum problem.

The Lagrangian

A fruitful way to reformulate the use of Lagrange multipliers is to introduce the notion of the Lagrangian associated with our constrained extremum problem.

Definition. The *Lagrangian* associated with our constrained extremum problem is the function $L \colon \Omega \times \mathbb{R}^m \to \mathbb{R}$ given by

$$L(\mathbf{v},\lambda) = J(\mathbf{v}) + \lambda_1 \varphi_1(\mathbf{v}) + \cdots + \lambda_m \varphi_m(\mathbf{v}),$$

with $\lambda = (\lambda_1, \dots, \lambda_m)$.

Critical Point of the Lagrangian

Proposition. There exists some $\mu = (\mu_1, \dots, \mu_m)$ and some $u \in U$ such that

$$dJ(u) + \mu_1 d\varphi_1(u) + \dots + \mu_m d\varphi_m(u) = 0$$

if and only if

$$dL(u,\mu)=0,$$

or equivalently

$$\nabla L(\mathbf{u}, \mu) = 0;$$

that is, iff (u, μ) is a *critical point* of the Lagrangian L.

Lagrangian System

If we write out explicitly the condition

$$dJ(u) + \lambda_1 d\varphi_1(u) + \cdots + \lambda_m d\varphi_m(u) = 0,$$

we get the $n \times m$ system

$$\frac{\partial J}{\partial x_1}(u) + \lambda_1 \frac{\partial \varphi_1}{\partial x_1}(u) + \dots + \lambda_m \frac{\partial \varphi_m}{\partial x_1}(u) = 0$$

$$\vdots$$

$$\frac{\partial J}{\partial x_n}(u) + \lambda_1 \frac{\partial \varphi_1}{\partial x_n}(u) + \dots + \lambda_m \frac{\partial \varphi_m}{\partial x_n}(u) = 0,$$

Lagrangian System

and it is important to note that the matrix of this system is the *transpose* of the Jacobian matrix of φ at u. If we write $\operatorname{Jac}(\varphi)(u) = \left((\partial \varphi_i/\partial x_j)(u)\right)$ for the Jacobian matrix of φ (at u), then the above system is written in matrix form as

$$\nabla J(u) + (\operatorname{Jac}(\varphi)(u))^{\top} \lambda = 0,$$

where λ is viewed as a column vector, and the Lagrangian is equal to

$$L(u,\lambda) = J(u) + (\varphi_1(u),\ldots,\varphi_m(u))\lambda.$$

The Lagrangian Technique

The beauty of the Lagrangian is that the constraints $\{\varphi_i(v)=0\}$ have been incorporated into the function $L(v,\lambda)$, and that the necessary condition for the existence of a constrained local extremum of J is reduced to the necessary condition for the existence of a local extremum of the *unconstrained L*.

One should be careful to check that the assumptions of the preceding theorem are satisfied (in particular, the linear independence of the linear forms $d\varphi_i$).

One should be careful to check that the assumptions of the preceding theorem are satisfied (in particular, the linear independence of the linear forms $d\varphi_i$).

Example. Let $J: \mathbb{R}^3 \to \mathbb{R}$ be given by

$$J(x, y, z) = x + y + z^2$$

and $g: \mathbb{R}^3 \to \mathbb{R}$ by

$$g(x, y, z) = x^2 + y^2.$$

Since g(x, y, z) = 0 iff x = y = 0, we have $U = \{(0, 0, z) \mid z \in \mathbb{R}\}$ and the restriction of J to U is given by $J(0, 0, z) = z^2$, which has a minimum for z = 0.

However, a "blind" use of Lagrange multipliers would require that there is some λ so that

$$\frac{\partial J}{\partial x}(0,0,\mathbf{z}) = \lambda \frac{\partial \mathbf{g}}{\partial x}(0,0,\mathbf{z}), \ \frac{\partial J}{\partial y}(0,0,\mathbf{z}) = \lambda \frac{\partial \mathbf{g}}{\partial y}(0,0,\mathbf{z}), \ \frac{\partial J}{\partial z}(0,0,\mathbf{z}) = \lambda \frac{\partial \mathbf{g}}{\partial z}(0,0,\mathbf{z}),$$

However, a "blind" use of Lagrange multipliers would require that there is some λ so that

$$\frac{\partial J}{\partial x}(0,0,\mathbf{z}) = \lambda \frac{\partial \mathbf{g}}{\partial x}(0,0,\mathbf{z}), \ \frac{\partial J}{\partial y}(0,0,\mathbf{z}) = \lambda \frac{\partial \mathbf{g}}{\partial y}(0,0,\mathbf{z}), \ \frac{\partial J}{\partial z}(0,0,\mathbf{z}) = \lambda \frac{\partial \mathbf{g}}{\partial z}(0,0,\mathbf{z}),$$

and since

$$\frac{\partial \mathbf{g}}{\partial \mathbf{x}}(\mathbf{x}, \mathbf{y}, \mathbf{z}) = 2\mathbf{x}, \quad \frac{\partial \mathbf{g}}{\partial \mathbf{y}}(\mathbf{x}, \mathbf{y}, \mathbf{z}) = 2\mathbf{y}, \quad \frac{\partial \mathbf{g}}{\partial \mathbf{z}}(0, 0, \mathbf{z}) = 0,$$

the partial derivatives above all vanish for x = y = 0, so at a local extremum we should also have

$$\frac{\partial J}{\partial x}(0,0,z) = 0, \quad \frac{\partial J}{\partial y}(0,0,z) = 0, \quad \frac{\partial J}{\partial z}(0,0,z) = 0,$$

but this is absurd since

$$\frac{\partial J}{\partial x}(x, y, z) = 1, \quad \frac{\partial J}{\partial y}(x, y, z) = 1, \quad \frac{\partial J}{\partial z}(x, y, z) = 2z.$$

the partial derivatives above all vanish for x=y=0, so at a local extremum we should also have

$$\frac{\partial J}{\partial x}(0,0,z) = 0, \quad \frac{\partial J}{\partial y}(0,0,z) = 0, \quad \frac{\partial J}{\partial z}(0,0,z) = 0,$$

but this is absurd since

$$\frac{\partial J}{\partial x}(x, y, z) = 1, \quad \frac{\partial J}{\partial y}(x, y, z) = 1, \quad \frac{\partial J}{\partial z}(x, y, z) = 2z.$$

The reader should enjoy finding the reason for the flaw in the argument.

Lagrangian Provides a Necessary Condition

Keep in mind that the preceding theorem gives only a necessary condition. The (u, λ) may not correspond to local extrema! Thus it is always necessary to analyze the local behavior of J near a critical point u.

Example. Let us apply the above method to the following example in which $E_1 = \mathbb{R}$, $E_2 = \mathbb{R}$, $\Omega = \mathbb{R}^2$, and

$$J(x_1, x_2) = -x_2$$

$$\varphi(x_1, x_2) = x_1^2 + x_2^2 - 1.$$

Observe that

$$U = \{(x_1, x_2) \in \mathbb{R}^2 \mid x_1^2 + x_2^2 = 1\}$$

is the unit circle, and since

$$\nabla \varphi(\mathbf{x}_1, \mathbf{x}_2) = \begin{pmatrix} 2\mathbf{x}_1 \\ 2\mathbf{x}_2 \end{pmatrix},$$

Observe that

$$U = \{(x_1, x_2) \in \mathbb{R}^2 \mid x_1^2 + x_2^2 = 1\}$$

is the unit circle, and since

$$\nabla \varphi(\mathbf{x}_1, \mathbf{x}_2) = \begin{pmatrix} 2\mathbf{x}_1 \\ 2\mathbf{x}_2 \end{pmatrix},$$

it is clear that $\nabla \varphi(x_1, x_2) \neq 0$ for every point $= (x_1, x_2)$ on the unit circle.

If we form the Lagrangian

$$L(x_1, x_2, \lambda) = -x_2 + \lambda(x_1^2 + x_2^2 - 1),$$

a necessary condition for J to have a constrained local extremum is that $\nabla L(x_1, x_2, \lambda) = 0$,

If we form the Lagrangian

$$L(x_1, x_2, \lambda) = -x_2 + \lambda(x_1^2 + x_2^2 - 1),$$

a necessary condition for J to have a constrained local extremum is that $\nabla L(x_1, x_2, \lambda) = 0$, so the following equations must hold:

$$2\lambda x_1 = 0$$
$$-1 + 2\lambda x_2 = 0$$
$$x_1^2 + x_2^2 = 1.$$

The second equation implies that $\lambda \neq 0$, and then the first yields $x_1 = 0$, so the third yields $x_2 = \pm 1$, and we get two solutions:

$$\lambda = \frac{1}{2},$$
 $(x_1, x_2) = (0, 1)$ $\lambda = -\frac{1}{2},$ $(x'_1, x'_2) = (0, -1).$

The second equation implies that $\lambda \neq 0$, and then the first yields $x_1 = 0$, so the third yields $x_2 = \pm 1$, and we get two solutions:

$$\lambda = \frac{1}{2},$$
 $(x_1, x_2) = (0, 1)$ $\lambda = -\frac{1}{2},$ $(x'_1, x'_2) = (0, -1).$

We can check immediately that the first solution is a minimum and the second is a maximum.

The second equation implies that $\lambda \neq 0$, and then the first yields $x_1 = 0$, so the third yields $x_2 = \pm 1$, and we get two solutions:

$$\lambda = \frac{1}{2},$$
 $(x_1, x_2) = (0, 1)$ $\lambda = -\frac{1}{2},$ $(x'_1, x'_2) = (0, -1).$

We can check immediately that the first solution is a minimum and the second is a maximum.

The reader should look for a geometric interpretation of this problem.

Example. Let us now consider the case in which J is a quadratic function of the form

$$J(\mathbf{v}) = \frac{1}{2} \mathbf{v}^{\top} A \mathbf{v} - \mathbf{v}^{\top} \mathbf{b},$$

where A is an $n \times n$ symmetric matrix, $b \in \mathbb{R}^n$, and the constraints are given by a linear system of the form

$$Cv = d$$
,

where C is an $m \times n$ matrix with m < n and $d \in \mathbb{R}^m$. We also assume that C has rank m.

Example. Let us now consider the case in which J is a quadratic function of the form

$$J(\mathbf{v}) = \frac{1}{2} \mathbf{v}^{\top} A \mathbf{v} - \mathbf{v}^{\top} \mathbf{b},$$

where A is an $n \times n$ symmetric matrix, $b \in \mathbb{R}^n$, and the constraints are given by a linear system of the form

$$Cv = d$$

where C is an $m \times n$ matrix with m < n and $d \in \mathbb{R}^m$. We also assume that C has rank m. In this case the function φ is given by

$$\varphi(\mathbf{v}) = (\mathbf{C}\mathbf{v} - \mathbf{d})^{\top},$$

and since

$$d\varphi(\mathbf{v})(\mathbf{w}) = \mathbf{C}^{\top}\mathbf{w},$$

the condition that the Jacobian matrix of φ at u have rank m is satisfied.

and since

$$d\varphi(\mathbf{v})(\mathbf{w}) = \mathbf{C}^{\top}\mathbf{w},$$

the condition that the Jacobian matrix of φ at u have rank m is satisfied. The Lagrangian of this problem is

$$L(\mathbf{v},\lambda) = \frac{1}{2}\mathbf{v}^{\top}A\mathbf{v} - \mathbf{v}^{\top}b + (C\mathbf{v} - \mathbf{d})^{\top}\lambda = \frac{1}{2}\mathbf{v}^{\top}A\mathbf{v} - \mathbf{v}^{\top}b + \lambda^{\top}(C\mathbf{v} - \mathbf{d}),$$

where λ is viewed as a column vector.

and since

$$d\varphi(\mathbf{v})(\mathbf{w}) = \mathbf{C}^{\top}\mathbf{w},$$

the condition that the Jacobian matrix of φ at u have rank m is satisfied. The Lagrangian of this problem is

$$L(\mathbf{v},\lambda) = \frac{1}{2}\mathbf{v}^{\top}A\mathbf{v} - \mathbf{v}^{\top}b + (C\mathbf{v} - \mathbf{d})^{\top}\lambda = \frac{1}{2}\mathbf{v}^{\top}A\mathbf{v} - \mathbf{v}^{\top}b + \lambda^{\top}(C\mathbf{v} - \mathbf{d}),$$

where λ is viewed as a column vector. Now because A is a symmetric matrix, it is easy to show that

$$\nabla L(v,\lambda) = \begin{pmatrix} Av - b + C^{\top}\lambda \\ Cv - d \end{pmatrix}.$$

Therefore, the necessary condition for constrained local extrema is

$$A\mathbf{v} + \mathbf{C}^{\mathsf{T}}\lambda = \mathbf{b}$$
$$C\mathbf{v} = \mathbf{d},$$

Therefore, the necessary condition for constrained local extrema is

$$A\mathbf{v} + \mathbf{C}^{\top} \lambda = \mathbf{b}$$
$$C\mathbf{v} = \mathbf{d},$$

which can be expressed in matrix form as

$$\begin{pmatrix} A & C^{\top} \\ C & 0 \end{pmatrix} \begin{pmatrix} v \\ \lambda \end{pmatrix} = \begin{pmatrix} b \\ d \end{pmatrix},$$

where the matrix of the system is a symmetric matrix.

This example will be further discussed in the next module. As we will show, the function J has a minimum iff A is positive definite, so in general, if A is only a symmetric matrix, the critical points of the Lagrangian do *not* correspond to extrema of J.
