Depth first search

$d(u)$  : time at which vertex  $u$  is discovered.

$f(u)$  : " " " " " & its neighbors  
are done exploring.

color  $(u)$  : white  $\rightarrow$  gray  $\rightarrow$  black

Running time:  $O(n+m)$

## Properties of DFS

When is a vertex  $v$  a descendant of vertex  $u$  in the DFS forest?  $\uparrow \uparrow$

Property 1:  $v$  is a descendant of  $u$  in the DFS forest iff  $v$  is discovered when  $u$  is gray.

Property 2 (Parenthesis theorem): Let  $u$  &  $v$  be

any two vertices in  $G$ . Then exactly one of

the following happens:

(i)  $\underbrace{d_u (u \ u) f_u}$

&  $v$  is a descendant of  $u$  in the DFS forest.

$\Rightarrow$   $\underbrace{d_v \ f_v}$   
 $(v \ v)$

$(u \ (v \ v) \ u)$

(ii)  $\overline{d_u \quad f_v}$  &  $u$  is a descendant of  $v$  in the DFS forest.

$\overline{d_u \quad f_u}$

(iii)  $\overline{d_u \quad f_u} \quad \overline{d_v \quad f_v}$  or  $\overline{d_u \quad f_u} \quad \overline{d_v \quad f_v}$

& neither  $v$  nor  $u$  is a descendant of the other in the DFS forest.

Proof sketch : WLOG, let  $d_u < d_v$ .

Case I :  $d_v > f_u$

Since  $v$  is discovered when  $u$ 's black,

$v$  is not a descendant of  $u$  in

the DFS forest. Similar reasoning to

argue that  $u$  is not a descendant of

$v$  in the DFS forest.

Case II :  $dv < fu$

Since  $v$  is discovered when  $u$ 's gray, by

property 1,  $v$  is a descendant of  $u$  in the DFS forest.  
It remains to show that  $f_v < f_u$ .  
When DFS is at vertex  $v$ , it finishes exploring all neighbours of  $v$ , colors  $v$  black before the search goes back to  $u$ . Hence  $f[v] < f[u]$ .

Corollary: Vertex  $v$  is a descendant of

$\otimes$

vertex  $u$  in the DFS forest iff

$$\underline{d_u} < d_v < f_v < f_u.$$

Property 3 (White Path Theorem)

Vertex  $v$  is a descendant of  $u$  in the DFS forest iff at  $d[u]$  there is a

white path (path consisting of white vertices) from

$u$  to  $v$  in  $G$ .

Proof: ( $\Rightarrow$ )  $v$  is a descendant of  $u$  in

the DFS forest  $\Rightarrow$  at  $d(u)$  there is a

white path from  $u$  to  $v$  in  $G$ .

Let  $P$  be the path from  $u$  to  $v$  in the DFS forest.

By property 1 (even property 2 will work),

$w$  is discovered when  $\text{color}(u)$  is grey,

which means that at time  $d(u)$ ,  
 $\text{color}(w)$  is white.

$(\Leftarrow)$  at time  $d(u)$  there is a white path  
from  $u$  to  $v$  in  $G \Rightarrow v$  is a descendant  
of  $u$  in the DFS forest.

Proof: Assume for contradiction that at time  $d(u)$

there is a white path from  $u$  to  $v$  in  $G$ ,

but  $v$  is not a descendant of  $u$  in the

DFS forest. Let  $P$  be the white

path from  $u$  to  $v$  in  $G$  at time  $d(u)$ .

Going from  $u$  towards  $v$  along  $P$ , let  $w$

be the first vertex that is not a descendant

of  $u$  in the DFS forest. Let  $x$  be

the vertex just before  $w$  in  $P$ .  $x$  is

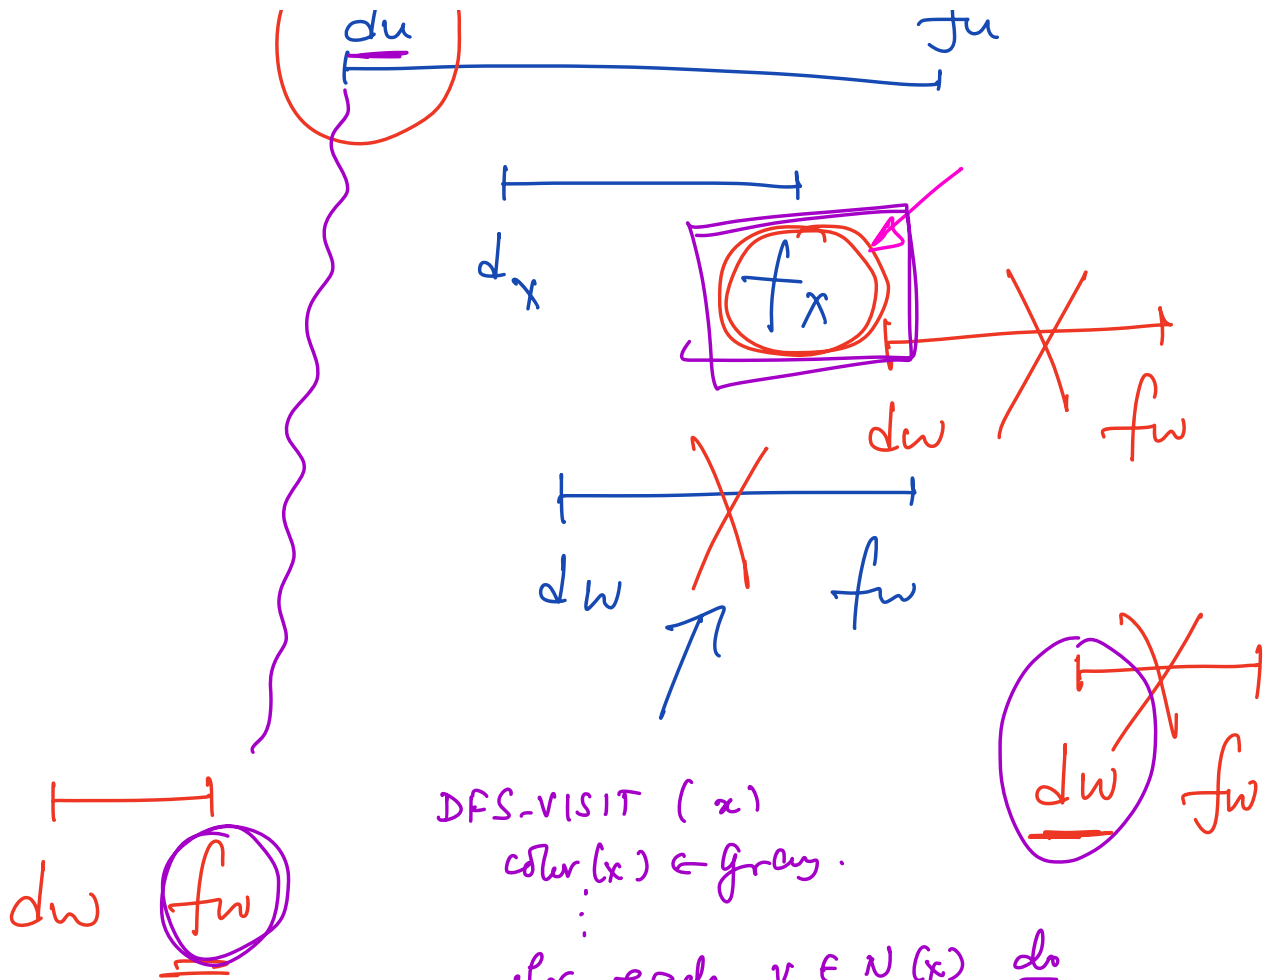

a descendant of  $u$  in the DFS

forest.

$P$

DFS-VISIT ( $x$ )  
 $color(x) \leftarrow gray.$

for each  $v \in N(x)$  do  
 if  $color(v) = \underline{white}$  then  
 $\pi[v] \leftarrow x$   
 DFS-VISIT( $v$ )  
 $color(x) \leftarrow black.$

Note that the interval  $[d_w, f_w]$  cannot

be contained in  $[d_u, f_u]$  (by the

Parenthesis theorem)

$[d_w, f_w]$  cannot be "after"  $f_u$ ,  
i.e.,  $d_w > f_u$  is not possible because  
 $w$  is a neighbour of  $x$  &  
 $x$  cannot have a white  
neighbour when it finishes.

Thus  $f_w < d_u$ , contradicting that there  
is a white path from  $u$  to  $w$  at time  
 $d[u]$ .

Edge Classification : During DFS, we can label

each edge of  $G$  as follows. Note that

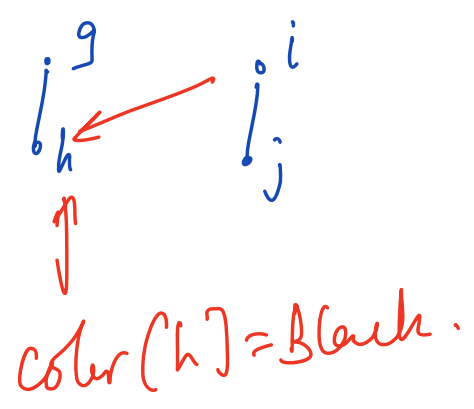

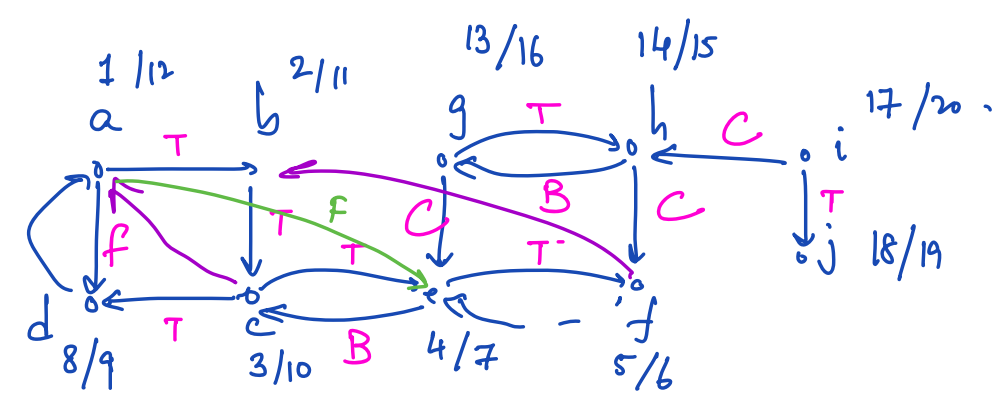

each edge is labeled the very first time it  
is explored. Edge  $e = (u, v)$  is a :

tree edge : if  $e$  is in the DFS forest.

back edge : if  $v$  is an ancestor of  $u$   
in the DFS forest.

forward edge : if  $v$  is a descendant of  
 $u$  in the DFS forest.

Cross edge : if it is none of the above.

Suppose  $e = (u, v)$  is a tree edge. Then when

$\wedge$

$e$  is explored first,  $\text{color}[v] = \underline{\text{white}}$ .

$e = (u, v)$  is a back edge. Then

where  $u$  is explored first  $\text{color}[v] = \text{Gray}$ .

$e$  is a forward edge. Then  
when  $e$  is explored first,  $\text{color}[v] = \underline{\text{Black}}$ .

Theorem:  $e = (u, v)$  is a forward edge ~~iff~~

when  $e$  is explored first,  $\text{color}[v] = \text{Black}$ .

&  $v$  is a descendant of  $u$  in the  
DFS forest.

Theorem: DFS on an undirected graph  $G$

yields Tree edges

Back edges  
Forward edges  
Cross edges .

Proof: Let  $e = (u, v)$  be any edge in  $G$ .  
WLOG, let  $d_u < d_v$ .

Claim:  $v$  is a descendant of  $u$  in the DFS forest.

Case I:  $v$  is a child of  $u$  in the DFS forest.  
 $e$  is a tree edge.

Case II:  $v$  is a descendant of  $u$  in the DFS forest, but  $v$  is not a child of  $u$ .

$\int v$

$e$  is first explored when the search is at  $v$ . At that time  $u$  is an ancestor of  $v$  in the DFS forest & hence  $e$  is a back edge. ✓.
