

Logistic Regression

Classification Based on Probability

- Instead of just predicting the class, give the probability of the instance being that class
 - i.e., learn $p(y \mid \boldsymbol{x})$
- Comparison to perceptron:
 - Perceptron doesn't produce probability estimate
 - Perceptron (and other discriminative classifiers) are only interested in producing a discriminative model
- Recall that:

$$0 \le p(\text{event}) \le 1$$

 $p(\text{event}) + p(\neg \text{event}) = 1$

Logistic Regression

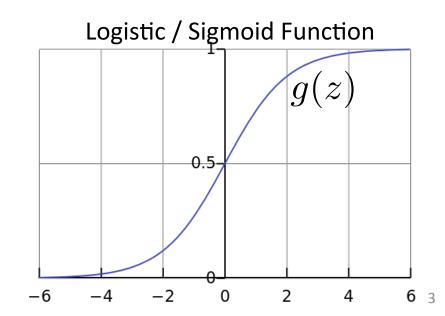

- Takes a probabilistic approach to learning discriminative functions (i.e., a classifier)
- $h_{m{ heta}}(m{x})$ should give $p(y=1\mid m{x};m{ heta})$
 - Want $0 \leq h_{m{ heta}}(m{x}) \leq 1$ -

Can't just use linear regression with a threshold

Logistic regression model:

$$h_{m{ heta}}(m{x}) = g(m{ heta}^\intercal m{x})$$
 $g(z) = rac{1}{1 + e^{-z}}$

$$h_{\boldsymbol{\theta}}(\boldsymbol{x}) = \frac{1}{1 + e^{-\boldsymbol{\theta}^{\mathsf{T}} \boldsymbol{x}}}$$

Interpretation of Hypothesis Output

$$h_{\boldsymbol{\theta}}(\boldsymbol{x})$$
 = estimated $p(y=1 \mid \boldsymbol{x}; \boldsymbol{\theta})$

Example: Cancer diagnosis from tumor size

$$\mathbf{x} = \begin{bmatrix} x_0 \\ x_1 \end{bmatrix} = \begin{bmatrix} 1 \\ \text{tumorSize} \end{bmatrix}$$
 $h_{\boldsymbol{\theta}}(\mathbf{x}) = 0.7$

→ Tell patient that 70% chance of tumor being malignant

Note that: $p(y = 0 | x; \theta) + p(y = 1 | x; \theta) = 1$

Therefore, $p(y = 0 \mid \boldsymbol{x}; \boldsymbol{\theta}) = 1 - p(y = 1 \mid \boldsymbol{x}; \boldsymbol{\theta})$

Another Interpretation

Equivalently, logistic regression assumes that

$$\log \underbrace{\frac{p(y=1\mid \boldsymbol{x};\boldsymbol{\theta})}{p(y=0\mid \boldsymbol{x};\boldsymbol{\theta})}}_{\text{odds of } y=1} = \theta_0 + \theta_1 x_1 + \ldots + \theta_d x_d$$

Side Note: the odds in favor of an event is the quantity p / (1 - p), where p is the probability of the event

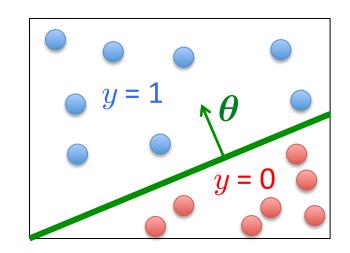

E.g., If I toss a fair dice, what are the odds that I will have a 6?

• In other words, logistic regression assumes that the log odds is a linear function of $oldsymbol{x}$

Logistic Regression

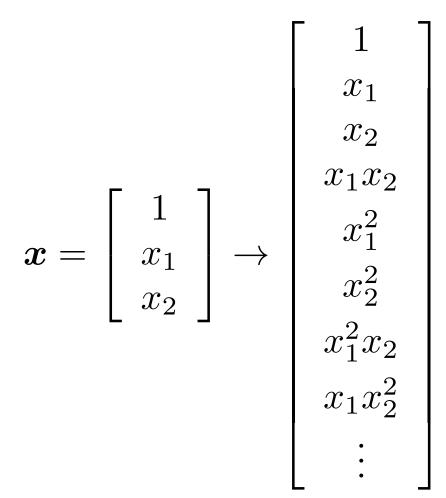

$$h_{m{ heta}}(m{x}) = g \ (m{ heta}^{\mathsf{T}} m{x})$$
 $g(z)$ $g($

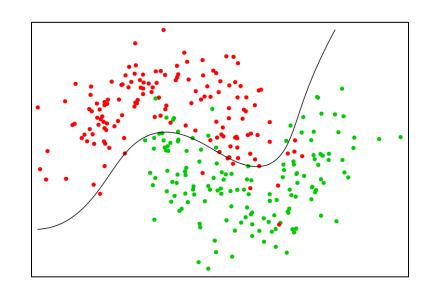

- Assume a threshold and...
 - Predict y = 1 if $h_{\theta}(x) \ge 0.5$
 - Predict y = 0 if $h_{\boldsymbol{\theta}}(\boldsymbol{x}) < 0.5$

Non-Linear Decision Boundary

 Can apply basis function expansion to features, same as with linear regression

Logistic Regression

• Given $\left\{\left(\boldsymbol{x}^{(1)}, y^{(1)}\right), \left(\boldsymbol{x}^{(2)}, y^{(2)}\right), \ldots, \left(\boldsymbol{x}^{(n)}, y^{(n)}\right)\right\}$ where $\boldsymbol{x}^{(i)} \in \mathbb{R}^d, \ y^{(i)} \in \{0, 1\}$

• Model:
$$h_{m{ heta}}(m{x}) = g\left(m{ heta}^{\intercal}m{x}
ight)$$

$$g(z) = \frac{1}{1+e^{-z}}$$

Logistic Regression Objective Function

Can't just use squared loss as in linear regression:

$$J(\boldsymbol{\theta}) = \frac{1}{2n} \sum_{i=1}^{n} \left(h_{\boldsymbol{\theta}} \left(\boldsymbol{x}^{(i)} \right) - y^{(i)} \right)^{2}$$

Using the logistic regression model

$$h_{\boldsymbol{\theta}}(\boldsymbol{x}) = \frac{1}{1 + e^{-\boldsymbol{\theta}^{\mathsf{T}} \boldsymbol{x}}}$$

results in a non-convex optimization

Deriving the Cost Function via Maximum Likelihood Estimation

- Likelihood of data is given by: $l(\pmb{\theta}) = \prod_{i=1} p(y^{(i)} \mid \pmb{x}^{(i)}; \pmb{\theta})$
- So, looking for the heta that maximizes the likelihood

$$\boldsymbol{\theta}_{\mathrm{MLE}} = \arg\max_{\boldsymbol{\theta}} l(\boldsymbol{\theta}) = \arg\max_{\boldsymbol{\theta}} \prod_{i=1} p(y^{(i)} \mid \boldsymbol{x}^{(i)}; \boldsymbol{\theta})$$

Can take the log without changing the solution:

$$\boldsymbol{\theta}_{\mathrm{MLE}} = \arg\max_{\boldsymbol{\theta}} \log\prod_{i=1}^{n} p(y^{(i)} \mid \boldsymbol{x}^{(i)}; \boldsymbol{\theta})$$

$$= \arg \max_{\boldsymbol{\theta}} \sum_{i=1}^{n} \log p(y^{(i)} \mid \boldsymbol{x}^{(i)}; \boldsymbol{\theta})$$

Deriving the Cost Function via Maximum Likelihood Estimation

Expand as follows:

$$\begin{aligned} \boldsymbol{\theta}_{\text{MLE}} &= \arg\max_{\boldsymbol{\theta}} \sum_{i=1}^{n} \log p(y^{(i)} \mid \boldsymbol{x}^{(i)}; \boldsymbol{\theta}) \\ &= \arg\max_{\boldsymbol{\theta}} \sum_{i=1}^{n} \left[y^{(i)} \log p(y^{(i)} = 1 \mid \boldsymbol{x}^{(i)}; \boldsymbol{\theta}) + \left(1 - y^{(i)}\right) \log \left(1 - p(y^{(i)} = 1 \mid \boldsymbol{x}^{(i)}; \boldsymbol{\theta})\right) \right] \end{aligned}$$

Substitute in model, and take negative to yield

Logistic regression objective:

$$\min_{\boldsymbol{\theta}} J(\boldsymbol{\theta})$$

$$J(\boldsymbol{\theta}) = -\sum_{i=1}^{n} \left[y^{(i)} \log h_{\boldsymbol{\theta}}(\boldsymbol{x}^{(i)}) + \left(1 - y^{(i)}\right) \log \left(1 - h_{\boldsymbol{\theta}}(\boldsymbol{x}^{(i)})\right) \right]$$

$$J(\boldsymbol{\theta}) = -\sum_{i=1}^{n} \left[y^{(i)} \log h_{\boldsymbol{\theta}}(\boldsymbol{x}^{(i)}) + \left(1 - y^{(i)}\right) \log \left(1 - h_{\boldsymbol{\theta}}(\boldsymbol{x}^{(i)})\right) \right]$$

Cost of a single instance:

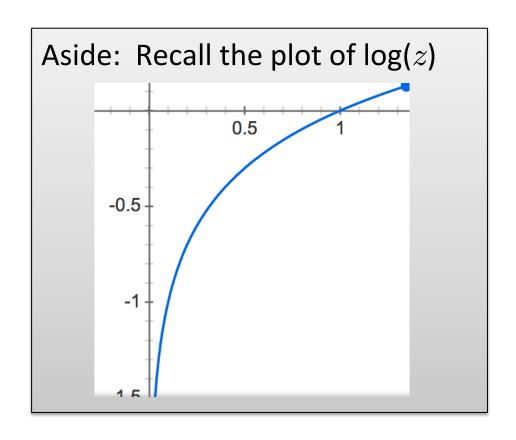

$$cost (h_{\theta}(\boldsymbol{x}), y) = \begin{cases} -\log(h_{\theta}(\boldsymbol{x})) & \text{if } y = 1\\ -\log(1 - h_{\theta}(\boldsymbol{x})) & \text{if } y = 0 \end{cases}$$

Can re-write objective function as

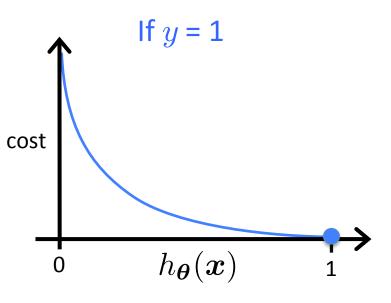

$$J(\boldsymbol{\theta}) = \sum_{i=1}^{n} \operatorname{cost} \left(h_{\boldsymbol{\theta}}(\boldsymbol{x}^{(i)}), y^{(i)} \right)$$

Compare to linear regression: $J(m{ heta}) = rac{1}{2n} \sum_{i=1}^n \left(h_{m{ heta}} \left(m{x}^{(i)}
ight) - y^{(i)}
ight)^2$

$$cost (h_{\theta}(\boldsymbol{x}), y) = \begin{cases} -\log(h_{\theta}(\boldsymbol{x})) & \text{if } y = 1\\ -\log(1 - h_{\theta}(\boldsymbol{x})) & \text{if } y = 0 \end{cases}$$

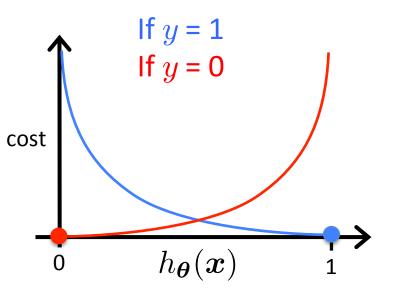

$$cost (h_{\theta}(\boldsymbol{x}), y) = \begin{cases} -\log(h_{\theta}(\boldsymbol{x})) & \text{if } y = 1\\ -\log(1 - h_{\theta}(\boldsymbol{x})) & \text{if } y = 0 \end{cases}$$

If y = 1

- Cost = 0 if prediction is correct
- As $h_{\boldsymbol{\theta}}(\boldsymbol{x}) \to 0, \cos t \to \infty$
- Captures intuition that larger mistakes should get larger penalties
 - e.g., predict $h_{oldsymbol{ heta}}(oldsymbol{x})=0$, but y = 1

$$cost (h_{\theta}(\boldsymbol{x}), y) = \begin{cases} -\log(h_{\theta}(\boldsymbol{x})) & \text{if } y = 1\\ -\log(1 - h_{\theta}(\boldsymbol{x})) & \text{if } y = 0 \end{cases}$$

If y = 0

- Cost = 0 if prediction is correct
- As $(1 h_{\theta}(\boldsymbol{x})) \to 0, \cos t \to \infty$
- Captures intuition that larger mistakes should get larger penalties

Regularized Logistic Regression

$$J(\boldsymbol{\theta}) = -\sum_{i=1}^{n} \left[y^{(i)} \log h_{\boldsymbol{\theta}}(\boldsymbol{x}^{(i)}) + \left(1 - y^{(i)}\right) \log \left(1 - h_{\boldsymbol{\theta}}(\boldsymbol{x}^{(i)})\right) \right]$$

We can regularize logistic regression exactly as before:

$$J_{\text{regularized}}(\boldsymbol{\theta}) = J(\boldsymbol{\theta}) + \lambda \sum_{j=1}^{d} \theta_j^2$$
$$= J(\boldsymbol{\theta}) + \lambda \|\boldsymbol{\theta}_{[1:d]}\|_2^2$$

Gradient Descent for Logistic Regression

$$J_{\text{reg}}(\boldsymbol{\theta}) = -\sum_{i=1}^{n} \left[y^{(i)} \log h_{\boldsymbol{\theta}}(\boldsymbol{x}^{(i)}) + \left(1 - y^{(i)}\right) \log \left(1 - h_{\boldsymbol{\theta}}(\boldsymbol{x}^{(i)})\right) \right] + \lambda \|\boldsymbol{\theta}_{[1:d]}\|_{2}^{2}$$

Want $\min_{oldsymbol{ heta}} J(oldsymbol{ heta})$

- Initialize θ
- Repeat until convergence

$$\theta_j \leftarrow \theta_j - \alpha \frac{\partial}{\partial \theta_i} J(\boldsymbol{\theta})$$

simultaneous update for $j = 0 \dots d$

Use the natural logarithm (In = \log_e) to cancel with the exp() in $h_{m{ heta}}(m{x})$

Gradient Descent for Logistic Regression

$$J_{\text{reg}}(\boldsymbol{\theta}) = -\sum_{i=1}^{n} \left[y^{(i)} \log h_{\boldsymbol{\theta}}(\boldsymbol{x}^{(i)}) + \left(1 - y^{(i)}\right) \log \left(1 - h_{\boldsymbol{\theta}}(\boldsymbol{x}^{(i)})\right) \right] + \lambda \|\boldsymbol{\theta}_{[1:d]}\|_{2}^{2}$$

Want $\min_{oldsymbol{ heta}} J(oldsymbol{ heta})$

- Initialize θ
- Repeat until convergence

(simultaneous update for $j = 0 \dots d$)

$$\theta_0 \leftarrow \theta_0 - \alpha \sum_{i=1}^n \left(h_{\boldsymbol{\theta}} \left(\boldsymbol{x}^{(i)} \right) - y^{(i)} \right)$$

$$\theta_j \leftarrow \theta_j - \alpha \left[\sum_{i=1}^n \left(h_{\boldsymbol{\theta}} \left(\boldsymbol{x}^{(i)} \right) - y^{(i)} \right) x_j^{(i)} - \frac{\lambda}{n} \theta_j \right]$$

Gradient Descent for Logistic Regression

- Initialize θ
- Repeat until convergence

(simultaneous update for $j = 0 \dots d$)

$$\theta_0 \leftarrow \theta_0 - \alpha \sum_{i=1}^n \left(h_{\boldsymbol{\theta}} \left(\boldsymbol{x}^{(i)} \right) - y^{(i)} \right)$$

$$\theta_j \leftarrow \theta_j - \alpha \left[\sum_{i=1}^n \left(h_{\boldsymbol{\theta}} \left(\boldsymbol{x}^{(i)} \right) - y^{(i)} \right) x_j^{(i)} - \frac{\lambda}{n} \theta_j \right]$$

This looks IDENTICAL to linear regression!!!

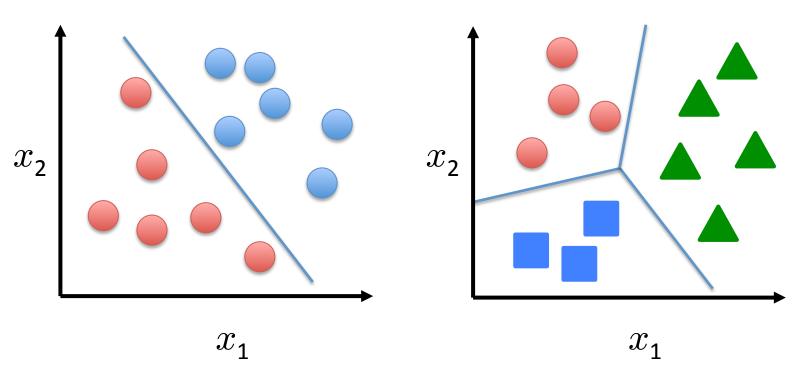

- Ignoring the 1/n constant
- However, the form of the model is very different:

$$h_{\boldsymbol{\theta}}(\boldsymbol{x}) = \frac{1}{1 + e^{-\boldsymbol{\theta}^{\mathsf{T}} \boldsymbol{x}}}$$

Multi-Class Classification

Binary classification:

Multi-class classification:

Disease diagnosis: healthy / cold / flu / pneumonia

Object classification: desk / chair / monitor / bookcase

Multi-Class Logistic Regression

For 2 classes:

$$h_{\boldsymbol{\theta}}(\boldsymbol{x}) = \frac{1}{1 + \exp(-\boldsymbol{\theta}^{\mathsf{T}}\boldsymbol{x})} = \underbrace{\frac{\exp(\boldsymbol{\theta}^{\mathsf{T}}\boldsymbol{x})}{1 + \exp(\boldsymbol{\theta}^{\mathsf{T}}\boldsymbol{x})}}_{\text{weight assigned to } y = 0} \underbrace{\frac{\exp(\boldsymbol{\theta}^{\mathsf{T}}\boldsymbol{x})}{1 + \exp(\boldsymbol{\theta}^{\mathsf{T}}\boldsymbol{x})}}_{\text{weight assigned to } y = 1}$$

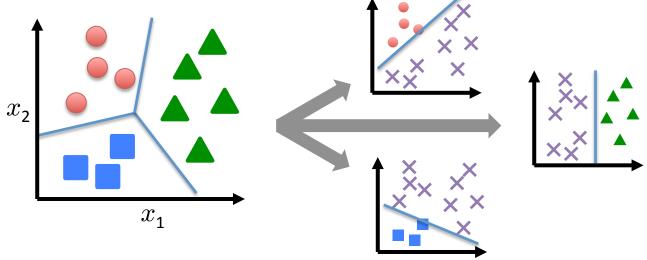

• For *C* classes {1, ..., *C*}:

$$p(y = c \mid \boldsymbol{x}; \boldsymbol{\theta}_1, \dots, \boldsymbol{\theta}_C) = \frac{\exp(\boldsymbol{\theta}_c^{\mathsf{T}} \boldsymbol{x})}{\sum_{c=1}^{C} \exp(\boldsymbol{\theta}_c^{\mathsf{T}} \boldsymbol{x})}$$

Called the softmax function

Multi-Class Logistic Regression

Split into One vs Rest:

• Train a logistic regression classifier for each class i to predict the probability that y = i with

$$h_c(\boldsymbol{x}) = \frac{\exp(\boldsymbol{\theta}_c^{\mathsf{T}} \boldsymbol{x})}{\sum_{c=1}^{C} \exp(\boldsymbol{\theta}_c^{\mathsf{T}} \boldsymbol{x})}$$

Implementing Multi-Class Logistic Regression

• Use
$$h_c(\boldsymbol{x}) = \frac{\exp(\boldsymbol{\theta}_c^\mathsf{T} \boldsymbol{x})}{\sum_{c=1}^C \exp(\boldsymbol{\theta}_c^\mathsf{T} \boldsymbol{x})}$$
 as the model for class c

- Gradient descent simultaneously updates all parameters for all models
 - Same derivative as before, just with the above $h_c(x)$
- Predict class label as the most probable label

$$\max_{c} h_c(\boldsymbol{x})$$
